What if app screens shipped like content?

```
{ "screen": "welcome",
  "version": 3,
  "root": {
    "type": "Hero", … } }
```

Swipe →

The problem

A one-line copy fix is a full app release.

Build it, wait for store review, roll it out, then wait for people to update. The old copy stays on screen the whole time.

src/screens/Welcome.tsx

```
- title="Fresh beans, on schedule"
+ title="Fresh beans, on your schedule"
```

Build → Store review → Rollout → Users update

Four steps to add one word.

How it works · 1

Register the components you already ship.

Your Hero, Card and Button stay in the app bundle. freshed learns their names and typed props, nothing more.

```
<FreshedProvider registry={[Hero, Card, Button, List]}>
```

Props

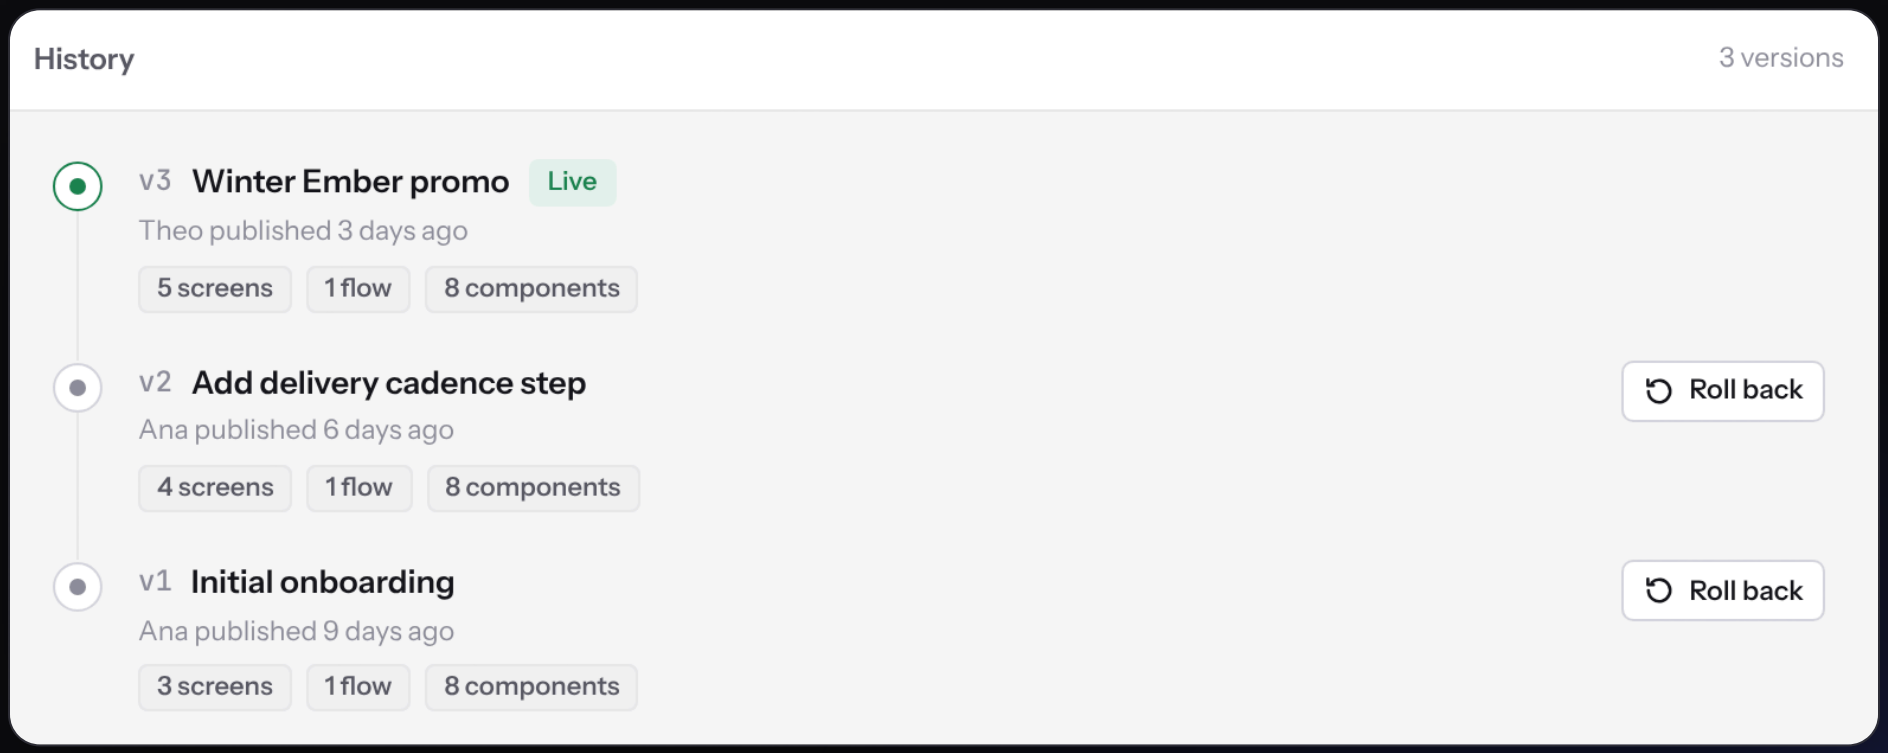

Name	Type	Default	Notes
`title`	`string`	none	Up to 60 characters

How it works · 2

Compose screens. Publish a version.

The preview uses the app's own renderer. Every publish is an **immutable version**; rolling back publishes a copy, so history only grows.

`GET /v1/flows/onboarding` · v3 live · ETag / 304

The design decision

Data only. Old builds never break.

No code is shipped at runtime. Each build says which protocol it reads, and the server **never sends a payload it can't render**.

This week's build · Freshed-Protocol: 2

Gets v4

The newest version it can read.

Two-year-old build · Freshed-Protocol: 1

Gets the newest protocol 1 version

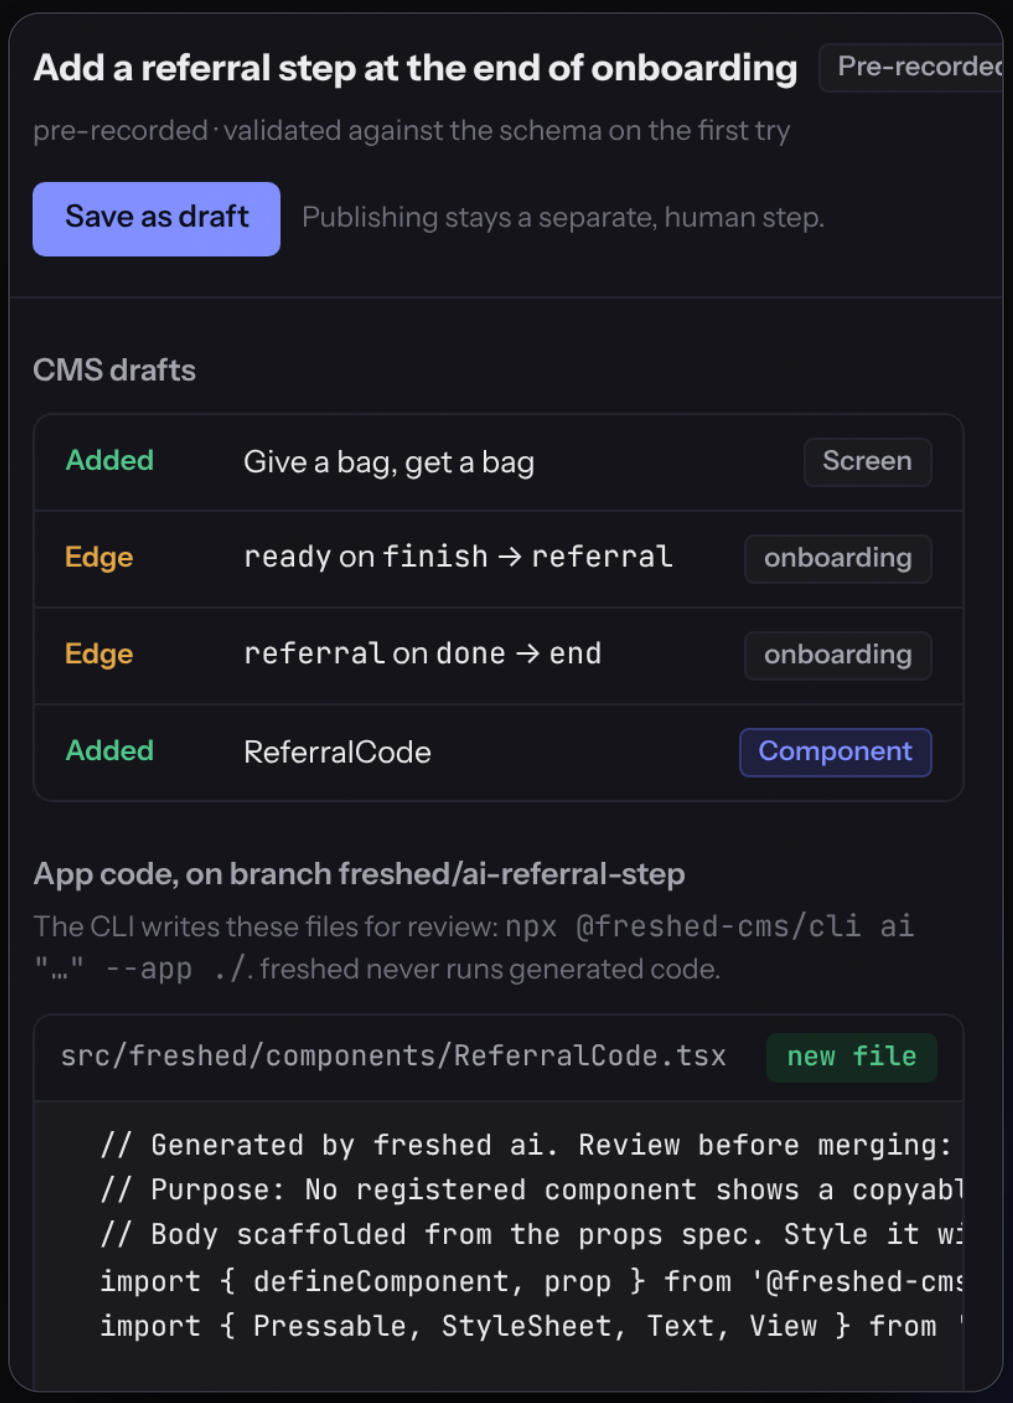

Unknown components fall back. It never crashes.

What makes it different

AI drafts. Humans publish.

One prompt becomes draft screens, plus component code on a review branch when the app is missing one.

- ✓ **Self-hosted.** Your Postgres, your server.
- ✓ **Your LLM key** stays in your browser tab.
- ✓ **No path** lets AI publish or merge.
